

Conceptual illustrations of the method and its evaluation questions. Robot poses, routes and response tables below are schematic, not measured results.

Begin with executed, legal motion alternatives

Place a beam around the achieved body envelope.
Check the whole entry-passage-return sequence in physics.

Long passages change how long adaptation is needed

Illustrative task	Walk	Short	Sustained
Open / easy	pass	pass	pass
Long low passage	fail	fail	pass
Transition-sensitive	pass	fail	fail

Complementarity means one fixed response cannot cover all tasks.
A decision also needs an observable cue before its legal deadline.
WAIT is useful only if a successful later continuation remains.

The scene and request must change successful behavior

Route alternatives are research targets, not demonstrated paths.

Reach the goal AND reduce speed AND maintain the hold.
Changing obstacles should change the route or posture.
Changing the goal should change the destination.

1 Construct and screen

- Conditional learned scene proposals
- Target clearance + contrast + visibility
- Keep motion ancestry and construction cost

2 Execute and bind the label

Same task, same prefix, named continuation
Passage / contact / goal-hold measurements
Successful task and recovery support checked

3 Learn and test in closed loop

Fresh learner states + qualified teaching + replay
Test scene/goal dependence and motor retention
Split by ancestry and task family, not rows

A useful self-learning loop requires executable targets, adequate public information, and examples from the learner's own state distribution.
